ECE:5845 Modern Databases

Movie Recommendations Final Project

Part 1: Upload data into database

1. Primary Database Choice: Neo4j

For my movie recommendation system, I decided to use Neo4j as the primary database. This is because the data is inherently graph-shaped: users rate movies, movies share genres, and we eventually wish to compute similarities & recommendations based on connections between users and items. A property-graph model along with Neo4j's Cypher query language makes it easy to express and display these relationships as well as running graph algorithms, like similarity or community detection, over the rating network.

2. Importing tables (had to change the memory in my config file for ratings to be properly imported):

```
1 LOAD CSV WITH HEADERS FROM 'file:///movies.csv' AS row
2 WITH row,
3     // Extract 4-digit year inside parentheses, e.g. "1995"
4     apoc.text.regexGroups(row.title, '.*\(((\d{4})\))') AS yearMatch
5 MERGE (m:Movie {movieId: toInteger(row.movieId)})
6 SET m.title = row.title,
7     m.genres = CASE
8         WHEN row.genres IS NULL OR row.genres = '(no genres listed)'
9         THEN []
10        ELSE split(row.genres, '|')
11    END,
12    m.year = CASE
13        WHEN yearMatch IS NULL OR size(yearMatch) = 0
14        THEN NULL
15        ELSE toInteger(yearMatch[0][1])
16    END;
17
```

Created 3,883 nodes, set 15,532 properties, added 3,883 labels Completed after 536 ms

- This was my import for the movies.csv

```
1 MATCH (m:Movie) RETURN count(m);
2
```

Table RAW

count(m)

1 3883

Started streaming 1 record after 16 ms and completed after 17 ms.

- This was me testing that the import worked properly

```
1 CALL (){
2   LOAD CSV WITH HEADERS FROM 'file:///ratings-1.csv' AS row
3
4   WITH row
5   MATCH (u:User {userId: toInteger(row.userId)})
6   MATCH (m:Movie {movieId: toInteger(row.movieId)})
7   CREATE (u)-[:RATED {
8     rating: toFloat(row.rating),
9     ratedAt: datetime({epochSeconds: toInteger(row.timestamp)})
10  }]->(m)
11 }
12 IN TRANSACTIONS OF 1000 ROWS;
13
```

Created 1,000,209 relationships, set 2,000,418 properties

Completed after 10,738 ms

- This was my import for the ratings-1.csv (I had to change my config file to get everything imported fine)

```
moviesprimary$ MATCH (r)-[:RATED]->(u) RETURN count(r) AS numRatings;
```

Table RAW

numRatings

1 2000418

Started streaming 1 record after 2 ms and completed after 3 ms.

```
moviesprimary$ MATCH (u:User) RETURN count(u) AS numUsers;
```

Table RAW

numUsers

1 6040

Started streaming 1 record after 1 ms and completed after 2 ms.

```
moviesprimary$ MATCH (m:Movie) RETURN count(m) AS numMovies;
```

Table RAW

numMovies

1 3883

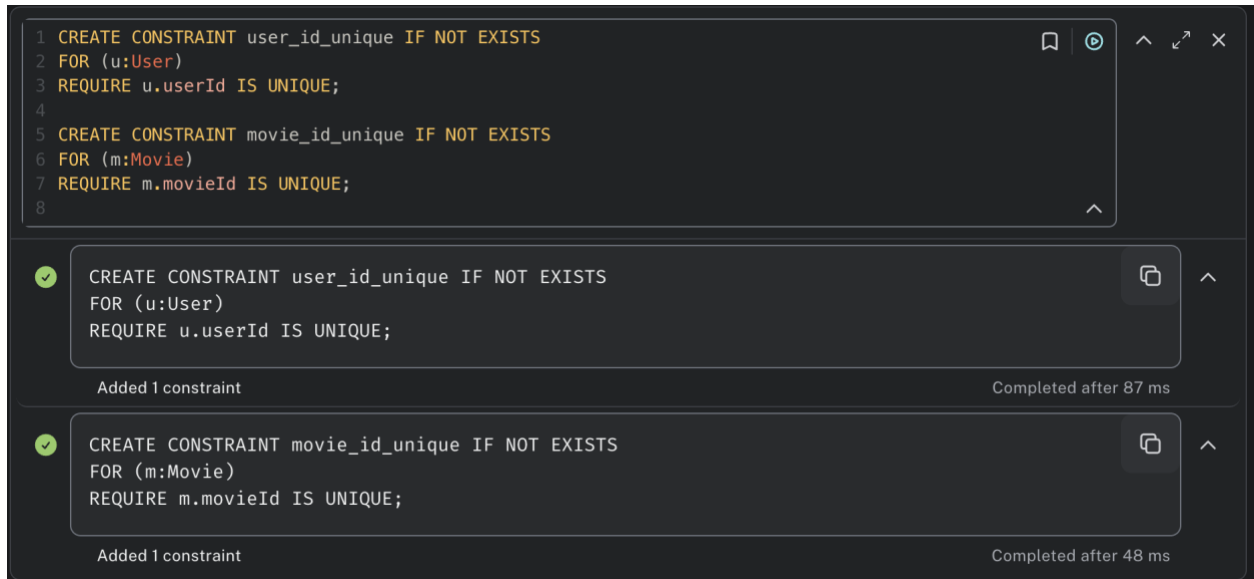

Started streaming 1 record after 2 ms and completed after 2 ms.

- This was me testing again to make sure that my import worked as intended

- I added in the movie and rating csv files into Neo4j's import directory. Then, I performed batched imports to avoid transaction memory limits.

3. Constraints for system:

I added the following constraints (before importing my data) to avoid duplicates and to speed up imports:

```
1 CREATE CONSTRAINT user_id_unique IF NOT EXISTS
2 FOR (u:User)
3 REQUIRE u.userId IS UNIQUE;
4
5 CREATE CONSTRAINT movie_id_unique IF NOT EXISTS
6 FOR (m:Movie)
7 REQUIRE m.movieId IS UNIQUE;
8
```

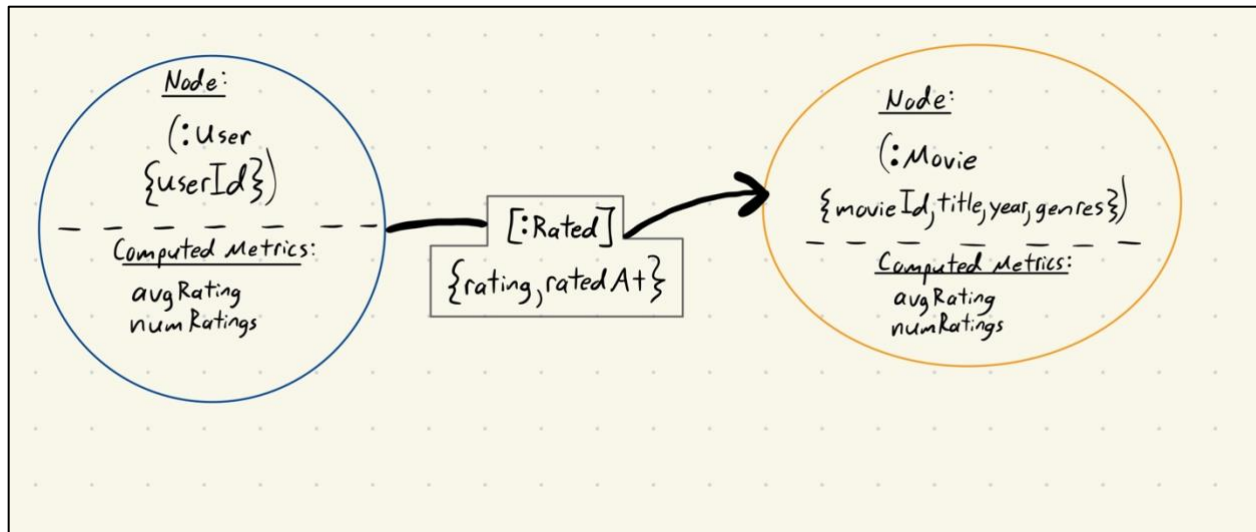

The screenshot shows the Neo4j Cypher console with two successful constraint creation queries. The first query, 'CREATE CONSTRAINT user_id_unique IF NOT EXISTS FOR (u:User) REQUIRE u.userId IS UNIQUE;', was completed after 87 ms. The second query, 'CREATE CONSTRAINT movie_id_unique IF NOT EXISTS FOR (m:Movie) REQUIRE m.movieId IS UNIQUE;', was completed after 48 ms. Both queries are marked with a green checkmark icon.

Part 2: Data design pattern and recommendation strategy

1.

- Data Model Design that supports movie recommendation queries:

To support the movie recommendation queries, I adopted a property-graph data model in Neo4j. In my model, users and movies are represented as nodes and ratings are represented as relationships. Each movie is modeled after a (:Movie {movieId, title, year, genres}) node. Each user is represented as a (:User {userId}) node. A user's interaction with a movie is stored through a [:RATED {rating, ratedAt}] relationship from a User node to a Movie node.

- Example figure of my Data Model Design

This structure can naturally fit collaborative filtering since it makes user-movie interactions explicit as edges. Similarity patterns begin to emerge as shared neighbors within the graph. To better support preference learning, I extended the nodes with aggregate metrics. For each user, I computed & stored avgRating and numRatings to capture the user's rating tendencies and activity level. For each movie, I computed avgRating and numRatings to represent overall quality and popularity. These metrics allow the recommendation system to leverage both global and personalized signals when ranking movies.

- Recommendation Strategy: User-Based Collaborative Filtering

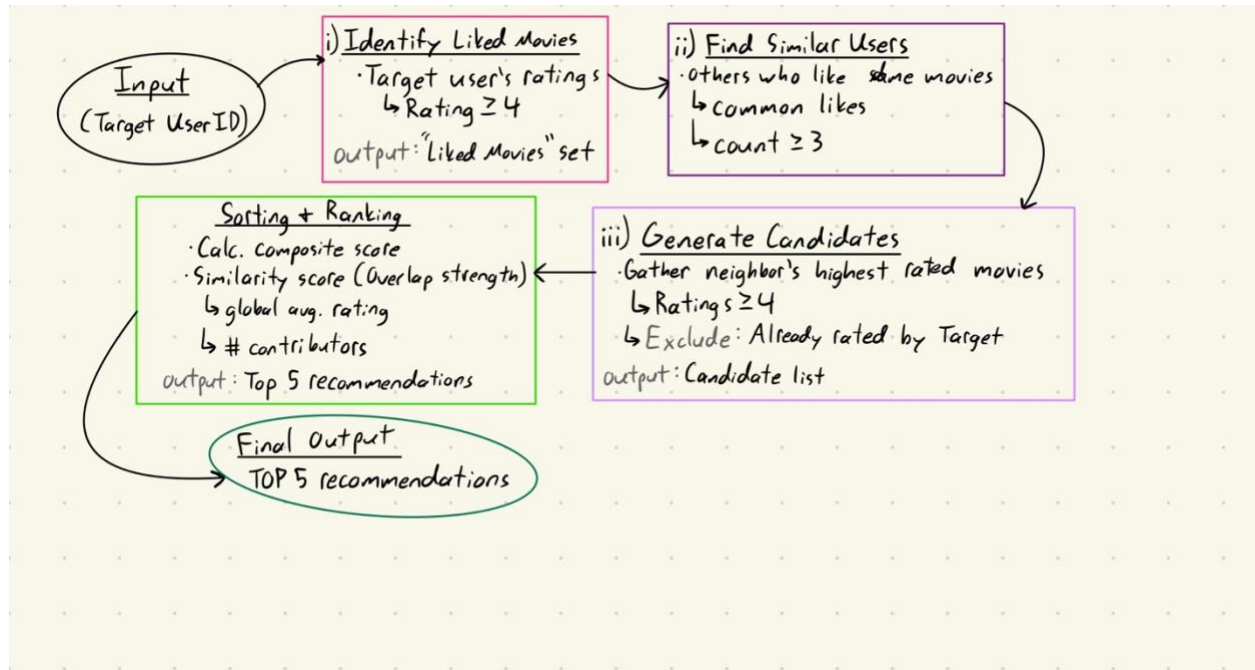

My system implements a user-based collaborative filtering (CF) approach via Ciper queries that were executed within my database in Neo4j. The strategy follows the following 3 conceptual steps:

- i. Identify movies the target user likes:
 - A movie is considered "liked" if the user rated it 4 or higher.
- ii. Find similar users
 - Users are considered similar if they also liked many of the same movies.
 - Similarity is measured by the number of commonly liked movies (commonLikes).
 - We apply a tunable similarity threshold ($\text{commonLikes} \geq 3$) to filter meaningful neighbors.

iii. Generate recommendations

- From the similar users, we gather additional movies they rated highly (rating ≥ 4) that the target user has never rated.
- Each candidate movie receives a composite score based on:
 - o similarityScore = sum of overlap strengths from all contributing similar users
 - o globalAvgRating = the movie's overall average rating in the dataset
 - o numContributors = number of similar users who support the recommendation

The top 5 movies ranked by these metrics are returned as the final recommendations.

- Example figure of my Recommendation Strategy as a flow chart

2. Structure data to incorporate similarity/preference metrics (avg rating + popularity):

To cover this section of the project, I decided to add per-user and per-movie statistics as properties:

- a. User preference metrics:

```
1 // Compute and store each user's average rating and number of ratings
2 MATCH (u:User)-[r:RATED]->()
3 WITH u, avg(r.rating) AS avgRating, count(r) AS numRatings
4 SET u.avgRating = avgRating,
5     u.numRatings = numRatings;
6
```

Set 12,080 properties Completed after 28,025 ms

b. Movie preference metrics:

```
1 // Compute and store each movie's average rating and number of ratings
2 MATCH (m:Movie)-[r:RATED]-()
3 WITH m, avg(r.rating) AS avgRating, count(r) AS numRatings
4 SET m.avgRating = avgRating,
5     m.numRatings = numRatings;
6
```

Set 7,412 properties Completed after 28,364 ms

- With these changes, my data now embeds preference metrics for the following:
 - Popularity: m.numRatings
 - Quality: m.avgRating
 - User bias: u.avgRating, u.numRatings
- These can be recomputed periodically as new ratings are added

3. Implement a recommendation approach using queries:

I decided to select the following strategy:

- Strategy: User-based collaborative filtering
 - A user “likes” a movie if rating ≥ 4
 - Similarity between two users = number of liked movies they share
 - Recommended movies: liked by similar users but unseen by the target user
 - Use m.avgRating and contributor counts as tiebreakers

4. Retrieve and provide the top 5 recommended movies for a user:

```

1 // User-based CF: top 5 recommendations for a target user
2 WITH 1 AS targetUserId      // can change the targetUserId to anything (just is 1 for now)
3 MATCH (u1:User {userId: targetUserId})-[r1:RATED]->(m:Movie)
4 WHERE r1.rating >= 4      // movies the target user likes
5
6 // find "similar" users who also like those movies
7 MATCH (other:User)-[r2:RATED]->(m)
8 WHERE other <> u1 AND r2.rating >= 4
9
10 // similarity = number of commonly liked movies
11 WITH u1, other, count(DISTINCT m) AS commonLikes
12 WHERE commonLikes >= 3    // similarity threshold (tuneable)
13
14 // from similar users, pull other movies they like
15 MATCH (other)-[r3:RATED]->(rec:Movie)
16 WHERE r3.rating >= 4
17     AND NOT (u1)-[:RATED]->(rec)    // ensure the target user has not rated rec
18
19 // aggregate a score per recommended movie
20 WITH rec,
21     sum(commonLikes)          AS similarityScore,
22     rec.avgRating             AS globalAvgRating,
23     count(DISTINCT other)     AS numContributors
24
25 RETURN rec.title              AS recommendedTitle,
26     similarityScore,
27     globalAvgRating,
28     numContributors
29 ORDER BY similarityScore DESC,
30     globalAvgRating DESC,
31     numContributors DESC
32 LIMIT 5;
33

```

- This was my query using my selected strategy (User-based collaborative filtering)

Table RAW				
	recommendedTitle	similarityScore	globalAvgRating	numContributors
1	"Star Wars"	49372	4.29297658862878	2250
2	"American Beauty (1999)"	46014	4.317386231038499	2307
3	"Raiders of the Lost Ark (1981)"	45932	4.477724741447882	2018
4	"Silence of the Lambs, The (1991)"	44382	4.3518231186966645	2029
5	"Shawshank Redemption, The (1994)"	43450	4.5545577009429685	1930

Started streaming 5 records after 46 ms and completed after 2,489 ms.

- These were the top 5 recommended movies for user 1
- As can be seen, this mimics my recommendation strategy using my data model design described in the first portion of this part of the project

Part 3: Integration with Redis for caching and search.

- I attached my associated python file in for the submission for this section of the project.

1.

```
Redis PING -> True

===== Redis + Neo4j Integration =====
1) Load / refresh movies from Neo4j into Redis
2) Create Redisearch index for movies
3) Search movies (full-text via Redis)

3. Rate a movie from the latest recommendations
0. Return to main menu
Choose an option: █

```

- In this portion, I select option 2 so I can see my top 5 recommended movies that I have yet to rate. Now, I select option 3 so I can rate one of those 5 movies. I select to rate the movie Cabaret Balkan (Bure Baruta), movie 1 in the list, and I give it a rating of 3 out of 5 stars because I decided that I didn't like the movie even though it was one of the top 5 movies recommended to me. Now, the average rating for the movie is updated to 3.52 and is stored in my Redis server. After this, I decided to select option 2 again so I could see how my top 5 recommended movie list has changed. Because I rated the last movie

not well, my list has changed which makes sense intuitively. Then, I decided to use option 1 to search for the movie that I rated 3 out of 5 stars before to see its updated associated data. As can be seen, the data is different since the average rating, my rating, and the “seen” section has been updated with the corresponding data.

```
